(54) Title: PROCESS FOR CONTINUOUS COOKING OF PULP

(57) Abstract

The present invention relates to a digester for continuous cooking under raised pressure and temperature of fibre material in a vertical digester (1), where input of fibre material and cooking liquid takes place at the top of the digester, withdrawal of spent cooking liquor is carried out from at least one digester strainer girdle (1D) between the top and the bottom of the digester, and fibre material is fed out from the bottom (1C) of the digester, wherein an existing digester (1) is fitted with an additional digester strainer girdle (2) above the lowest strainer girdle (1B) of the digester so that the temperature in all the participatory cooking zones in the digester can be kept at essentially the same temperature level.

FIG.1 1/3

FIG. 2 2/3

3/3

FIG. 3

Process for continuous cooking of pulp

5 Technical field

This invention relates to a method for continuous cooking of pulp, which method improves pulp quality so that subsequently none chlorine containing bleaching processes
10 can be used in order to reach full brightness for a pulp having desired strength and quality properties.

Background and problem

15 The environmental authorities are placing ever more stringent demands on the pulp industry to decrease the use of chemicals which can be damaging to the environment, such as, for example, chlorine. Thus, permitted discharges of organic chlorine compounds in the waste
20 water from bleaching plants, following on from the cooking process, have been decreased progressively and are now at such a low level that pulp factories have in many cases stopped using organic chlorine compounds as bleaching agents. In addition, market forces are tending progressively to increase the demand for paper products
25 which are not bleached with chlorine or chlorine containing bleaching agents.

The pulp industry is therefore searching for methods
30 which allow bleaching of pulp without using these chemicals. The lignox method (see SE-A 8902058), in which, inter alia, bleaching is carried out with hydrogen peroxide, may be mentioned as an example of such a method. Ozone is another interesting bleaching chemical
35 which is also gaining increased application. It is thus possible, using bleaching chemicals of this nature, to

achieve those brightnesses which are required for marketable pulp, i.e. 89 ISO and greater, without using chlorine containing bleaching agents.

There is, however, a problem in using presently known
5 bleaching procedures with these bleaching chemicals which do not contain chlorine, namely that they have a relatively large effect in diminishing the quality of the pulp fibres.

10 From EP 476 230 there is known a method for continuous cooking under raised pressure and temperature of fibre material in a vertical digester, where input of fibre material and cooking liquid takes place at the top of the digester, withdrawal of spent cooking liquor is carried
15 out from at least one digester strainer girdle between the top and the bottom of the digester, and fibre material is fed out from the bottom of the digester, wash liquid is supplied at the bottom of the digester, which wash liquid is withdrawn from a lowermost strainer
20 girdle, whereby the digester comprises a digester strainer girdle between said lowest strainer girdle and said strainer girdle for spent liquor, which in-between strainer girdle is attached to a heating device.
This known method indicates that the quality of the pulp
25 fibres after continuous cooking can be somewhat improved if cooking liquid is added to the wash circulation in the lower part of the digester and the temperature is raised. In order to be able to bleach pulp to sufficient brightness without the use of chlorine containing bleaching
30 agents, however, this known method is not always sufficient.

Solution and advantages

35 By means of experiments which have been conducted under the auspices of Kamyr AB, it has been found, surpris-

ingly, that extremely good results, with regard to delignification and strength properties, can be obtained if the pulp is cooked at the same temperature level in principally the whole of the digester, i.e. if essentially
5 the same temperature is maintained in all cooking zones, and if a certain quantity of alkali is also supplied to the lowest zone in the digester, which zone is normally used for counter-current washing. Owing to the fact that essentially the same temperature level is maintained in
10 virtually the whole of the digester, very extensive delignification can be achieved at a relatively low temperature. Besides this, it has been found that the strength properties are affected in a particularly favourable manner, that a higher yield of the crude fibre
15 product is obtained and that the quantity of reject material decreases. These advantages are most clearly apparent from the diagrams shown in the Figures 1 and 2, which show comparative values between pulp (softwood) which has been cooked using a conventional, modified cooking technique and pulp which has been cooked using the process
20 according to the invention, (in a similar digester, i.e. with a concurrent upper cooking zone, a central counter-current cooking zone and a bottom counter-current washing zone) in which a constant temperature level of about
25 + 155°C has been maintained in the whole digester.

The invention mainly relates to a method for achieving a cooking according to the new process, but also to a preferred arrangement for achieving a cooking according to
30 the invention in particular with regard to digesters built according to an older principle and consisting of an upper concurrent cooking zone and a lower counter-current washing zone. Such an arrangement is necessary since certain practical problems arise as a consequence
35 of an isothermal cooking process. The first such problem is the difficulty of efficiently reaching and maintaining

the temperature in the lower part of the digester, i.e. that part which is normally employed for washing. The said problem is solved by creating a more efficient circulation and thus temperature distribution in the lower part (the high-heat or washing zone) of the digester. This is achieved by arranging a strainer girdle adjacent above the lowest strainer girdle, somewhere between the strainer girdle for withdrawal of spent liquor and said lowest strainer girdle, whereby said in-between strainer is positioned in such a manner that its lowest part is positioned less than 5 meters from the upper part of said lowest strainer and that cooking liquid is supplied to that liquid flow which has its temperature controlled by means of the heating device, which flow discharges adjacent the level of said lowest strainer in by means of a central pipe, so that the temperature in the cooking zone immediately above the said additional digester strainer girdle can be maintained at essentially the same temperature level as the remaining cooking zone or cooking zones of the digester.

In this context it has been found to be advantageous to use digester strainer girdle consisting of oval or circular strainers, in particular so-called manhole strainers, in connection with converting existing digesters, both of the modified type and the older type, for operation according to the new process.

Short description of the figures

In Figure sheet 1, a comparison is made in three diagrams between isothermal cooking and so-called modified conventional cooking (MCC). Figure sheet 2 shows a diagram which describes degree of delignification and viscosity (the viscosity is normally regarded as indicating the strength properties of the pulp), and Figure 3 shows how,

in a preferred manner, an existing digester can be converted, using manhole strainers, to be operated according to the novel process.

5 Detailed description

The first figure page shows three diagrams which compare different results obtained with isothermal cooking and conventional modified cooking (MCC). These surprisingly
10 positive results show, according to the upper diagram, that, with a given amount of added alkali, substantially lower kappa numbers are obtained using isothermal cooking. Furthermore, the second diagram shows that manifestly improved strength properties are obtained when
15 cooking down to the same kappa number. In addition, the third diagram shows that there is also the advantage that the quantity of reject wood (shives) decreases. If the fact is also taken into account that overall substantial energy savings are made when the temperature level is
20 kept constant, it is evident that the results may be regarded as being surprisingly positive. Figure 2 additionally demonstrates that, using the method according to the invention, very low kappa numbers are reached while at the same time retaining good pulp
25 strength (viscosity round about 1000) after oxygen delignification. Thus, when employing the method according to the invention, so-called environmentally friendly bleaching chemicals, such as peroxide and ozone, can be employed in subsequent bleaching stages without risking
30 too low a strength for bleaching up to the level of brightness, and therewith also the level of purity, which the market demands.

Figure 3 shows the lower part of a digester 1, which is intended to represent an existing digester shell (which
35 definitely is higher than 20 metres normally higher than 30 metres and usually about 40 metres and more and having

a diameter of 1/10 of the height) on which has been arranged a new digester strainer girdle 2 in order to be able to raise the temperature in the counter-current zone. The digester has a lowest strainer girdle (1B) and one strainer girdle (1D) for withdrawal of spent liquor and is of the type which has an upper concurrent part and a lower counter-current part. In such a digester, full cooking temperature is normally maintained in the concurrent zone (i.e. about 162°C for hardwood and about 168 °C for softwood) while in the counter-current part, which in the main is a washing zone, the temperature is about 135°C on a level with the lower strainer.

In the text following, the counter-current zone of the digester which has been fitted with a further strainer girdle will be referred to as a cooking zone, even if it is to be considered as a washing zone according to conventional operation.

The new digester strainer girdle 2 consists of a number of so-called manhole strainers 2A for withdrawal of cooking liquid in the lower part of the digester and is arranged immediately above the lower strainer girdle 1B, preferably at most 5 metres above more preferred 1,5 metres above and more preferably at most 1 metre above, measured from the upper edge of the lower digester strainer girdle to the lower edge of the newly fitted digester strainer girdle. Wash liquor is supplied to the lower part of the digester through an inflow arrangement 4 attached in the vicinity of the bottom 1A of the digester and cooking liquid (alkali addition) through the central pipes 5A, 5B. The cooked pulp is taken out from the bottom of the digester via a conduit 1E.

One of these central pipes, 5A, which belongs to the original system of the digester, penetrates down to the lower strainer girdle 1B of the digester, after which the liquid, after heating via the first heat exchanger 6A, discharges through the said pipe on a level with the

latter digester strainer girdle. Subsequently, a part of the liquid flows in a counter-current direction upwards towards the newly fitted digester strainer girdle 2. The liquid withdrawn from this system passes through the said conduit arrangement 3 and is heated via a heat exchanger 6B to the desired temperature before it discharges, via a second, newly fitted central pipe 5B, immediately above the newly fitted digester strainer girdle 2. A part of the cooking liquid supplied in this manner, which liquid has thus achieved the desired temperature, chemical strength and distribution (spreading) over the whole of the cross-section of the digester, continues to flow upwards in the digester. In order to achieve even distribution the flow within each cooking circulation, would normally exceed $1 \text{ m}^3/\text{h}$. In a central digester strainer girdle 1D, the spent cooking liquid, together with undissolved wood material, is drawn off for further treatment. The surface of each strainer element 2A is made relatively small, preferably less than 0.3 m^2 . An advantage of strainer elements of small area is that efficient back flushing can be achieved, which is often of great importance if the circulation flow is to function efficiently. The new strainer girdle 2 is preferably fitted with ring pipes 2C from which an individual conduit goes to each and every one of the strainer elements 2A. Using such a construction, and a valve arrangement belonging to it, a limited number (for example 4) of strainer units 2A can be efficiently back-flushed at a time. Owing to the relatively small total strainer surface which is back-flushed under these circumstances (for example 1 m^2), a very efficient back-flushing which cleans the strainers is obtained, thereby ensuring that the circulation is highly efficient.

The invention is not limited by that which has been described above, but can be varied within the scope of the subsequent patent claims. Thus, an existing digester of

the MCC type can also be arranged in accordance with the invention, where, therefore, the digester has an upper concurrent part, a central, mainly counter-current, part and a lower counter-current part, where addition of a
5 part of the cooking liquid takes place in the said lower counter-current part, the so-called high-heat zone. A digester of the so-called hydraulic type, with a lower temperature in the upper part (the impregnation zone), may also advantageously be fitted with a digester
10 strainer girdle according to the invention for cooking according to the invention, so-called isothermally. Additionally the method may be used in connection with all types of cooking liquid, even if the method is principally intended for producing sulphate pulp. In addition,
15 it is obvious to the person skilled in the art that the invention is not limited to the above mentioned exemplifying temperature levels. In this connection, however, it is important that the average temperature level in the digester preferably exceeds $+150^{\circ}\text{C}$ but is lower than
20 $+165^{\circ}\text{C}$, and preferably is between $150-155^{\circ}\text{C}$ for hardwood and between $160-165^{\circ}\text{C}$ for softwood, and furthermore that the average temperature in the cooking zone/zones is preferably about $+151^{\circ}\text{C} \pm 1^{\circ}\text{C}$, when the wood is hardwood, and that the average temperature in a digester is
25 $+159^{\circ}\text{C} \pm 1^{\circ}\text{C}$, when the wood is softwood. In addition, it is understood that strainers deviating from a circular form, for example oval strainers, or even rectangular may also be used, whereby, for technical reasons related to the construction, the smallest radius of curvature should
30 preferably not fall below 0.2 m.

Finally, it is pointed out that new digesters can naturally also be fitted with strainer girdles, and be operated, according to the invention. Furthermore it is
35 understood that more than one strainer girdle can be arranged between the strainer girdle withdrawing spent

cooking liquor and the lowest strainer girdle. It is also evident for the skilled man that more than one strainer girdle may be used for withdrawing spent liquor.

- This lowest strainer girdle is normally positioned within
5 its lower edge about 1-2 metres above the welded seam that joins the spherical bottom position with the cylindrical digester shell, but in extreme designs the distance might be as short as 0.5 metres and as long as 5 metres.

PATENT CLAIMS

1. Method for continuous cooking under raised pressure and temperature of fibre material in a vertical digester (1), where input of fibre material and cooking liquid takes place at the top of the digester, withdrawal of spent cooking liquor is carried out from at least one digester strainer girdle (1D) between the top and the bottom of the digester, and fibre material is fed out from the bottom (1C) of the digester, wash liquid is supplied at the bottom (1A) of the digester, which wash liquid is withdrawn from a lowest strainer girdle (1B), whereby the digester comprises a digester strainer girdle (2) between said lowest strainer girdle (1B) and said strainer girdle for spent liquor (1D), which in-between strainer girdle (2) is attached to a heating device (6B) characterised in that said in-between strainer girdle (2) is positioned in such a manner that its lowest part is positioned less than 5 metres from the upper part of said lowest strainer girdle (1B) and that cooking liquid (1G) is supplied to that liquid flow which has its temperature controlled by means of said heating device (6B), which flow discharges adjacent the level of said lowest strainer girdle (1B) by means of a central pipe (5A), so that the temperature in the cooking zone immediately above said in-between strainer girdle (2) can be maintained at essentially the same temperature level as the remaining cooking zone or cooking zones of the digester.

30

2. Method according to Claim 1, characterised in that the said digester strainer girdle (2) consists of a number of strainers (2A) having circular or oval form designed to withdraw displaced liquid for supply to a central pipe (5B).

35

3. Method according to Claim 1, characterised in that the distance between the upper edge of the

lowest digester strainer girdle (1B) and the lower edge of the digester strainer girdle in-between (2) is less 2 m and preferably less than 1 m.

5 4. Method according to Claim 1, c h a r a c t e r i-
s e d in that the temperature of the fibre material and
upwardly flowing liquid which is located adjacent above
the upper edge of the in-between digester strainer girdle
(2A) deviates from the temperature in the remaining
10 cooking zone or cooking zones by at most 4°C, preferably
2°C, most preferred 1°C.

5. Method according to Claim 1, c h a r a c t e r i-
s e d in that the digester comprises at least one
15 conduit arrangement (1F or 1G), for addition of cooking
liquid in connection with one of the said lowest strainer
girdles (1B or 2).

6. Method according to Claim 1, c h a r a c t e r i-
20 s e d in that the digester comprises at least two
conduit arrangements (1F, 1G), for addition of cooking
liquid in connection with at least one of said lowest
strainer girdles (1B or 2), preferably for addition of
cooking liquid to both of said lowest strainer girdles
25 (1B and 2).

7. Method according to Claim 1, c h a r a c t e r i-
s e d in that said in-between strainer girdle (2) is
newly fitted to an existing digester shell.
30

8. Method according to Claim 2, c h a r a c t e r i-
s e d in that said central pipe (5B) discharges
immediately above the said in-between digester strainer
girdle (2).
35

9. Method according to Claim 2 or 7, c h a r a c-
t e r i s e d in that said central pipe (5B) is newly
fitted to an existing digester shell.

AMENDED CLAIMS

[received by the International Bureau on 18 April 1994 (18.04.94);
original claims 1-9 replaced by amended claims 1-8 (3 pages)]

1. Method for continuous cooking under raised pressure and temperature of fibre material in a vertical digester (1), where input of fibre material and cooking liquor takes place at the top of the digester, withdrawal of spent cooking liquor is carried out from at least one strainer girdle (1D) between the top and the bottom of the digester, and fibre material is fed out from the bottom (1C) of the digester, wash liquor (4) is supplied at the bottom (1A) of the digester, liquor is withdrawn from a lowest digester strainer girdle (1B) which liquor, after heating via a first heat exchanger (6A), by means of a first central pipe (5A) discharges on a level with the said lowest digester strainer girdle (1B), and whereby the digester (1) comprises an upper digester strainer girdle (2) between said lowest digester strainer girdle (1B) and said strainer girdle for spent liquor (1D), which upper digester strainer girdle (2) withdraws liquor which via a second heat exchanger (6B), and a second central pipe (5B) discharges preferably immediately above the said upper digester strainer girdle (2), and that the digester comprises at least one conduit arrangement (1F or 1G), for addition of cooking liquor in connection with one of the said digester strainer girdles (1B or 2)
- characterised in that the cooking is carried out isothermally, whereby said upper digester strainer girdle (2) is positioned in such a manner that its lowest part is positioned less than 5 metres from the upper part of said lowest digester strainer girdle (1B), whereby an efficient circulation and temperature distribution is created in the lower part of the digester and whereby said from the central pipes (5A 5B) discharged liquors are heated to such a temperature that the temperature in the cooking zone immediately above said upper digester strainer girdle (2) is maintained at essentially the same temperature level as the remaining cooking zone or

cooking zones of the digester.

2. Method according to Claim 1, c h a r a c t e r i -
r i s e d in that the said upper digester strainer
5 girdle (2) consists of a number of strainers (2A) having
circular or oval form designed to withdraw displaced
liquor for supply to a central pipe (5B).
3. Method according to Claim 1, c h a r a c t e r i -
10 s e d in that the distance between the upper edge of the
lowest digester strainer girdle (1B) and the lower edge
of the upper digester strainer girdle (2) is less 2 m and
preferably less than 1 m.
- 15 4. Method according to Claim 1, c h a r a c t e r i -
s e d in that the temperature of the fibre material and
upwardly flowing liquor which is located adjacent above
the upper edge of the upper digester strainer girdle (2A)
deviates from the temperature in the remaining cooking
20 zone or cooking zones by at most 4°C, preferably 2°C,
most preferred 1°C.
5. Method according to Claim 1, c h a r a c t e r i -
s e d in that the digester comprises at least one
25 conduit arrangement (1F or 1G), preferably two (1F, 1G),
for addition of cooking liquor in connection with one of
the said digester strainer girdles (1B or 2).
6. Method according to Claim 1, c h a r a c t e r i -
30 s e d in that said upper digester strainer girdle (2) is
newly fitted to an existing digester shell.
7. Method according to Claim 2, c h a r a c t e r i -
s e d in that said central pipe (5B) discharges
35 immediately above the said upper digester strainer girdle
(2).

8. Method according to Claim 2 or 7, c h a r a c-
t e r i s e d in that said central pipe (5B) is newly
fitted to an existing digester (1).
